Unit 10: Recursion

Adapted from:
1) Building Java Programs: A Back to Basics Approach by Stuart Reges and Marty Stepp
2) Runestone CSAwesome Curriculum

https://longbaonguyen.github.io
Recursion

**recursion**: The definition of an operation in terms of itself.
- Solving a problem using recursion depends on solving smaller occurrences of the same problem.

**recursive programming**: Writing methods that call themselves to solve problems recursively.
- An equally powerful substitute for *iteration* (loops)
- Particularly well-suited to solving certain types of problems
Why learn recursion?

• "cultural experience" - A different way of thinking of problems
• Can solve some kinds of problems better than iteration
• Leads to elegant, simplistic, short code (when used well)
• Many programming languages ("functional" languages such as Scheme, ML, and Haskell) use recursion exclusively (no loops)
Recursion and cases

• Every recursive algorithm involves at least 2 cases:
  – **base case**: A simple occurrence that can be answered directly.

  – **recursive case**: A more complex occurrence of the problem that cannot be directly answered, but can instead be described in terms of smaller occurrences of the same problem.

  – Some recursive algorithms have more than one base or recursive case, but all have at least one of each.

  – A crucial part of recursive programming is identifying these cases.
You are lined up in front of your favorite store for Black Friday deals. The line is long and wraps around the building so that you cannot see the front of the line. How do you figure out your position without getting out of line?

Answer: Ask the person in front of you.

**Base case:** If a customer is at the front of the line and someone asks him for his position, he’ll “return” 1.

**Recursive case:** If a customer is at position n and someone asks him for his position, he’ll ask the person in front of him.

Note: The recursive case reduces an n problem to an n-1 problem. Each person repeated asks until the question reaches the first person in line. He will answer informing the person behind him, who will then inform the person behind him, etc... until the answer reaches you.
• Consider the following method to print a line of * characters:

```java
// Prints a line containing the given number of stars.  
// Precondition: n >= 0
public static void printStars(int n) {
    for (int i = 0; i < n; i++) {
        System.out.print("*");
    }
    System.out.println();  // end the line of output
}
```

• Write a recursive version of this method (that calls itself).
  – Solve the problem without using any loops.
  – Hint: Your solution should print just one star at a time.
The real, even simpler, base case is an $n$ of 0, not 1:

```java
public static void printStars(int n) {
    if (n == 0) {
        // base case; just end the line of output
        System.out.println();
    }
    else {
        // recursive case; print one more star
        System.out.print("*");
        printStars(n - 1);
    }
}
```

- **Recursion Zen**: The art of properly identifying the best set of cases for a recursive algorithm and expressing them elegantly.
Write a recursive method `pow` accepts an integer base and exponent and returns the base raised to that exponent.

- Example: `pow(3, 4)` returns 81
- Solve the problem recursively and without using loops.

```
// Precondition: exponent >= 0, base > 0
public static int pow(int base, int exponent) {
    if (exponent == 0) {
        // base case; any number to 0th power is 1
        return 1;
    }
    else {
        // recursive case:  x^y = x * x^(y-1)
        return base * pow(base, exponent - 1);
    }
}
```
• Consider the following recursive method:

```java
public static int mystery(int n) {
    if (n < 10) {
        return n;
    } else {
        int a = n / 10;
        int b = n % 10;
        return mystery(a + b);
    }
}
```

– What is the result of the following call?

`mystery(648)`
Recursion Tree Diagram 1

mystery(648)

9

a = 64
b = 8
return mystery(72)

9

a = 7
b = 2
return mystery(9)

9

return 9

9 propagates all the up to mystery(648) which equals 9.

Note: This is the simplest example where the same number propagates up. Usually, at each step, more math is performed on each answer.
int mystery(int n) {
    if (n == 1 || n == 2)
        return 2 * n;
    else
        return mystery(n - 1) - mystery(n - 2);
}

What is the result of the following call?
mystery(4);

See the next slide for a way to visualize this one. Watch the animation on the powerpoint version of this lecture.
Recursion Tree Diagram 2

See the powerpoint version of this lecture for the animation. If you're having a hard time visualizing recursion, I highly recommend watching the animation of this slide.
Consider the following recursive method:

```java
public static int mystery(int n) {
    if (n < 10) {
        return (10 * n) + n;
    } else {
        int a = mystery(n / 10);
        int b = mystery(n % 10);
        return (100 * a) + b;
    }
}
```

What is the result of the following call?

`mystery(348)`
Recursion Tree Diagram 3

See the powerpoint version of this lecture for the animation. If you're having a hard time visualizing recursion, I highly recommend watching the animation of this slide.
**Merge sort**

**merge sort**: Repeatedly divides the data in half, sorts each half, and combines the sorted halves into a sorted whole.

The algorithm:
- Divide the list into two roughly equal halves.
- Sort the left half.
- Sort the right half.
- Merge the two sorted halves into one sorted list.

- Often implemented recursively.
- An example of a "divide and conquer" algorithm.
  - Invented by John von Neumann in 1945
Merge sort example

<table>
<thead>
<tr>
<th>index</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>22</td>
<td>18</td>
<td>12</td>
<td>-4</td>
<td>58</td>
<td>7</td>
<td>31</td>
<td>42</td>
</tr>
</tbody>
</table>

```
22 18 12 -4
  |     |
  22 18
  |     |
  22 18
```

```
58 7 31 42
  |     |

![Graph showing runtime vs input size](image-url)
The `Arrays` and `Collections` classes in `java.util` have a static method `sort` that sorts the elements of an array/list.

Arrays.sort() is used for arrays.

```java
String[] words = {"foo", "bar", "baz", "ball"};

Arrays.sort(words);
System.out.println(Arrays.toString(words));
```

// [ball, bar, baz, foo]

```java
int index = Arrays.binarySearch(words, "bar"); // 1
```
• Collections.sort() is used for arraylists.

```java
List<String> words2 = new ArrayList<String>();
for (String word : words) {
    words2.add(word);
}

Collections.sort(words2);

System.out.println(words2);
// [ball, bar, baz, foo]
```
Lab 1: Fractal Circles

Use Processing to write the recursive method to print out a recursive pattern of circles of decreasing radii. Since this is a static image, you don't need draw(). Use the following complete template:

```java
void setup() {
    background(255);
    size(600, 600);
    circle(width/2, width/4, 10);
}

void circle(int x, int radius, int depth) {
    // fill in your code
    //(just a 4 lines of code inside an if conditional!)
}
```
Lab 1

The previous template with correct completed code produces:
Lab 2: Sierpinski Triangle

Use Processing to write the recursive method to draw the Sierpinski triangle.

You may use the template on the next slide. (just 5 lines of code!)
void setup() {
    background(255);
    size(600,600);
    fill(0,255,0);
    // draw the first green triangle.
    triangle(0,height, width/2, 0, width, height);

    // start the recursive call.
    fractal(0,height, width/2, 0, width, height, 6);
}

void fractal(int x1, int y1, int x2, int y2, int x3,
             int y3, int n) {

    // fill in your code
    //(just a 5 (algebraically careful) lines of code
    // inside an if conditional!)
